

1 Overview

1.1 Location `$<APPSDKSamplesInstallPath>\samples\aparapi\examples`

1.2 How to Run See the *Getting Started* guide for how to build samples. You first must compile the sample.

Use the command line to change to the directory where the executable is located. The pre-compiled sample jar is at

`$<APPSDKSamplesInstallPath>\samples\aparapi\examples\Convolution`

Under Windows, type the following command(s).

1. `conv.bat`
Performs convolution on the default image `testcard.jpg`.
2. `conv.bat -h`
This prints the help file.

Under Linux, type the following command(s).

1. `./conv.sh`
Performs convolution on the default image `testcard.jpg`.
2. `./conv.sh -h`
This prints the help file.

1.3 Command Line Options Table 1 lists, and briefly describes, the command line options.

Table 1 Command Line Options

Short Form	Long Form	Description
-h	--help	Shows all command options and their respective meaning.
	--device	Devices on which the program is to be run. Acceptable values are <code>cpu</code> or <code>gpu</code> .
-q	--quiet	Quiet mode. Suppresses all text output.
-e	--verify	Verify results against reference implementation.
-t	--timing	Print timing.
-v	--version	AMD APP SDK version string.
-i	--iterations	Number of iterations for kernel execution.

2 Introduction

Using Image filters on photos, desired effects can be sought by applying these filters either on the entire image or just a portion of it. In image filtering, a 2D filter matrix is applied on the 2D image. Then, for every pixel of the image, take the sum of products, where each product is the value of the current pixel or a neighbor of it, with the corresponding value of the filter matrix. The center of the filter matrix must be multiplied with the current pixel, the other elements of the filter matrix with corresponding neighbor pixels. This is called Convolution or Correlation. The difference between Convolution and Correlation is that for Convolution a mirror of the filter matrix is used. The filters with convolution are relatively simple, and its size is uneven, so that it has a center, for example 3x3, 5x5, and 7x7. Depending on the weights chosen, a filter can be made to function as a blur, emboss, pass-through, darken filter, brighten filter, etc. Applying these filters per pixel is still a time-consuming operation Parallel processing using Aparapi can be used to reduce the execution time.

3 Implementation Details

In this example, the `com.amd.aparapi.Kernel` is extended in `ConvolutionKernel.java`. The `public void Kernel.run()` method is overridden in this source file, and convolution using 3x3 image filter per pixel is implemented in this method. A given pixel is filtered only if it is not a boundary pixel; that is, it has valid pixels surrounding it. A call to the `Kernel.execute(range)` method is made in this class, which is used to initiate the execution of `Kernel.run()` over the range 0...n. This class also implements the reference implementation, which is used for verifying that the Aparapi-calculated filtered images match that of the reference. `ConvolutionFilter.java` holds filter weights for a 3x3 filter to be applied to each pixel in the image. This example applies BLUR, EMBOSS, and NONE (pass through) filters on an input image. It repeats the application of these filters on the image over the given number of iterations. `Convolution.java` implements the control code and displays the original image along with NONE, BLUR, and EMBOSS filtered images in a 2x2 grid.

In case the `--quiet` or `--verify` option is used, the display window is closed automatically; otherwise, it waits for the user to close the display window.

4 Recommended Input Option Settings

For best performance, enter the following on the command line: `-i 10 -q -t`
